Introduction to dislocations Dislocations are crucially important in determining the mechanical behaviour of materials. This teaching and learning package provides an introduction to dislocations and their motion through a crystal. A 'bubble raft' model is used to demonstrate some of the features of dislocations and other lattice defects.

Introduction to Dislocations was first published in 1965 in a series aimed at undergraduate and postgraduate students in metallurgy and materials science and related disciplines. At the time, the subject was maturing and it was expected that 'dislocation concepts' would remain a core discipline for a very long time. As expected, the book has been, and remains, an important undergraduate text ...

Patellar dislocations most commonly occur in the lateral direction. Medial dislocations, intra-articular and superior dislocations are rare. The vastus medialis obliquus or VMO is the most distal portion of the quadriceps muscle and exerts a medially directed force that helps keep the patella in position.

The concept of the dislocation was invented independently by Orowan, Taylor and Polanyi in 1934 as a way of explaining two key observations about the plastic deformation of crystalline material: The stress required to plastically deform a crystal is much less than the stress one calculates from considering a defect-free crystal structure
